Frustrated by slow thinking after traumatic brain injury?

After traumatic brain injury, thoughts may not come as quickly as they used to. Slow processing speed can interfere with thinking, memory, and organization - in essence, with doing what you need to do in your life. Kessler Foundation needs your help to research a computer program that may improve processing speed after traumatic brain injury.

Volunteers must be between 18-59, have no other neurological illness, and no history of psychiatric problems. The study involves five weeks of computer activities and four testing sessions. Volunteers will be compensated for their time.

The study's principal investigator is Nancy Chiaravalloti, PhD.
